

- * Draw a decision tree diagram to predict number of rows to play based on weather conditions like outlook, temperature, humidity, windy, consider databas shown below

| Outlook | Temperature | Humidity | Windy | Hours to Play |
|----------|-------------|----------|-------|---------------|
| Rainy | Hot | High | False | 25 |
| Rainy | Hot | High | True | 30 |
| Overcast | Hot | High | False | 46 |
| Sunny | Mild | High | False | 45 |
| Sunny | Cool | Normal | False | 52 |
| Overcast | Cool | Normal | True | 43 |
| Rainy | Mild | High | False | 35 |
| Rainy | Cool | Normal | False | 38 |
| Sunny | Mild | Normal | False | 46 |
| Rainy | Mild | Normal | True | 48 |
| Overcast | Mild | High | True | 52 |
| Overcast | Hot | Normal | False | 44 |
| Sunny | Mild | High | True | 30 |
| Sunny | Cool | Normal | True | 23 |

Termination criteria: $CV \leq 10\%$ or minimum number of Sample

Calculating mean, standard deviation (SD), co-efficient of variation

$$\text{mean} = \frac{\sum x}{n} = \frac{557}{14} = 39.78$$

$$SD = \sqrt{\frac{\sum (x - \text{mean})^2}{n}} = 9.67$$

$$CV = \frac{SD}{\text{mean}} \times 100 = \frac{9.67}{39.78} \times 100 = 24.30$$

Now, dataset is split into different attributes. The SD of each branch is calculated.

$$SD(\text{attr}) = \sum W(\text{branch}) \cdot SD(\text{branch})$$

and the result SDR (standard deviation reduction) is calculated, $SDR = SD - SD(\text{attr})$

$$\therefore SD = 9.67$$

Outlook:-

| Outlook | mean | SD | CV | n | W(v) |
|----------|-------|------|------|---|------|
| Rainy | 35.2 | 8.7 | 24.7 | 5 | 5/14 |
| Overcast | 46.25 | 4.03 | 8.72 | 4 | 4/14 |
| Sunny | 39.2 | 12.2 | 81.0 | 5 | 5/14 |

$$\therefore SD(\text{outlook}) = \frac{5}{14} * 8.7 + \frac{4}{14} * 4.03 + \frac{5}{14} * 12.2 = 8.59$$

$$SDR(\text{outlook}) = SD - SD(\text{outlook}) = 9.67 - 8.59 = 1.08$$

Temperature:-

| Temperature | mean | SD | CV | n | W(v) |
|-------------|-------|-------|-------|---|------|
| Hot | 36.25 | 10.34 | 30.6 | 4 | 4/14 |
| Cool | 39 | 12.14 | 31.1 | 4 | 4/14 |
| Mild | 42.6 | 8.38 | 19.65 | 6 | 6/14 |

$$\therefore SD(\text{temperature}) = \frac{4}{14} * 10.34 + \frac{4}{14} * 12.14 + \left(\frac{6}{14}\right) * 8.38 = 10.01$$

$$SDR(\text{temperature}) = SD - SD(\text{temperature}) = 9.67 - 10.01 = -0.34$$

Humidity:-

| Humidity | mean | SD | CV | n | w(CV) |
|----------|------|-------|-------|---|-------|
| High | 27.5 | 10.11 | 26.92 | 7 | 7/14 |
| Normal | 4.2 | 9.4 | 22.4 | 7 | 7/14 |

$$\therefore SD(\text{humidity}) = \frac{7}{14} * 10.11 + \frac{7}{14} * 9.4 = 9.77$$

$$SDR(\text{humidity}) = SD - SD(\text{humidity}) = 9.67 - 9.77 = -0.1$$

Windy:-

| Windy | mean | S.D | CV | n | w(CV) |
|-------|------|------|------|---|-------|
| True | 37.6 | 11.6 | 30.8 | 6 | 6/14 |
| False | 41.3 | 8.41 | 20.3 | 8 | 8/14 |

$$\therefore SD(\text{windy}) = \frac{6}{14} * 11.6 + \frac{8}{14} * 8.41 = 9.77$$

$$\therefore SDR(\text{windy}) = SD - SD(\text{windy}) = 9.67 - 9.77 = -0.1$$

$$SDR(\text{outlook}) = 1.08$$

$$SDR(\text{windy}) = -0.1$$

$$SDR(\text{Temperature}) = -0.34$$

$$SDR(\text{humidity}) = -0.1$$

The value that has highest SDR is consider as root node (i.e decision node)

Considering termination criteria

CV is 10% or CV is ($n \leq 4$)

Outlook

Over cast has CV of 8%, which is less than threshold.

④

value - therefore, we need not go for further splitting.

We need to split sunny and rainy columns

| Outlook | Temperature | Humidity | Windy | Hours played |
|---------|-------------|----------|-------|--------------|
| Sunny | mild | high | False | 45 |
| Sunny | cool | Normal | False | 52 |
| Sunny | cool | Normal | True | 23 |
| Sunny | mild | Normal | False | 46 |
| Sunny | mild | high | True | 30 |

$$\therefore \text{mean} = 39.2; \text{SD} = 12.2; \text{CV} = 31.0$$

Temperature:-

| Temperature | mean | SD | CV | n | w(v) |
|-------------|------|-------|-------|---|------|
| Mild | 40.3 | 8.96 | 22.23 | 3 | 3/5 |
| Cool | 37.5 | 20.50 | 54.66 | 2 | 2/5 |

$$\text{SD}(\text{temperature}) = \frac{2}{5} * 8.96 + \frac{3}{5} * 20.5 = 13.576$$

$$\text{SDR}(\text{temperature}) = \text{SD} - \text{SD}(\text{temperature}) = 12.2 - 13.576 = -1.37$$

Humidity:-

| Humidity | mean | SD | CV | n | w(v) |
|----------|------|-------|-------|---|------|
| high | 37.5 | 10.6 | 28.26 | 2 | 2/5 |
| Normal | 40.3 | 15.30 | 37.96 | 3 | 3/5 |

$$\text{SD}(\text{humidity}) = \frac{2}{5} * 10.6 + \frac{3}{5} * 15.30 = 13.42$$

$$\text{SDR}(\text{humidity}) = \text{SD} - \text{SD}(\text{humidity}) = 12.2 - 13.42 = -1.22$$

Windy:-

5

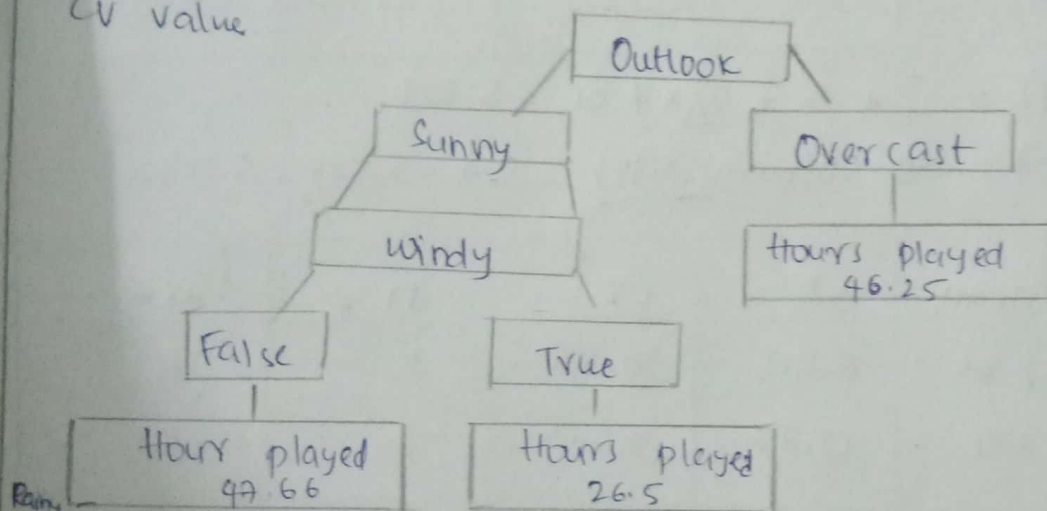

| Windy | mean | SD | CV | n | w(v) |
|-------|-------|------|-------|---|------|
| False | 47.66 | 3.78 | 7.94 | 3 | 3/5 |
| True | 26.5 | 4.94 | 18.65 | 2 | 2/5 |

$$SD(\text{windy}) = \frac{3}{5} * 3.78 + \frac{2}{5} * 4.94 = 4.23$$

$$SDR(\text{windy}) = SD - SD(\text{windy}) = 12.2 - 4.23 = 7.97$$

In outlook, among temperature, humidity and windy SDR value is high for windy $SDR = 7.97$

Then, check for CV value both true and false satisfy the CV value

Rainy

| Outlook | Temperature | Humidity | Windy | Hours played |
|---------|-------------|----------|-------|--------------|
| Rainy | hot | high | False | 25 |
| Rainy | hot | high | True | 30 |
| Rainy | mild | high | False | 35 |
| Rainy | cool | Normal | False | 38 |
| Rainy | mild | Normal | True | 48 |

$$\text{mean} = 35.2, SD = 8.7, CV = 24.7$$

Temperature:-

| Temperature | mean | SD | CV | n | w(w) |
|-------------|------|------|--------|---|------|
| Hot | 27.5 | 3.53 | 12.83 | 2 | 2/5 |
| mild | 41.5 | 9.19 | 22.144 | 2 | 2/5 |
| cool | 38 | 0 | 0 | 1 | 1/5 |

$$SD(Temp) = \frac{2}{5} * 3.53 + \frac{2}{5} * 9.19 + \frac{1}{5} * 0 = 5.088$$

$$SDR(Temperature) = 8.7 - 5.088 = 3.612$$

Humidity:-

| Humidity | mean | SD | CV | n | w(w) |
|----------|------|------|-------|---|------|
| High | 30 | 5 | 16.66 | 3 | 3/5 |
| Normal | 43 | 7.07 | 16.44 | 2 | 2/5 |

$$SD(humidity) = \frac{3}{5} * 5 + \frac{2}{5} * 7.07 = 5.828$$

$$SDR(humids) = SD - SD(humidity) = 8.7 - 5.828 = 2.872$$

Windy:-

| Windy | mean | SD | CV | n | w(w) |
|-------|-------|-------|-------|---|------|
| False | 32.66 | 6.80 | 20.85 | 3 | 3/5 |
| True | 39 | 12.72 | 32.5 | 2 | 2/5 |

$$SD(windy) = \frac{3}{5} * 6.80 + \frac{2}{5} * 12.72 = 9.68$$

$$SDR(windy) = 8.7 - 9.68 = -0.98$$

The SDR value is high for temperature among Temperature, humidity & windy. Then check for cv value of hot, mild and cold satisfy the cv value

* Design tree diagram to predict number of hours to play based on weather conditions.
